Quick Facts

About...Vibriosis

What is vibriosis?

Vibriosis (vib-ree-OH-sis) is an infection caused by *Vibrio* bacteria. These bacteria are found in water, especially water where fresh and salt water mix (estuary or brackish water). *Vibrio* bacteria are more common in water during summer.

What are the symptoms of vibriosis?

- Vomiting
- Diarrhea (sometimes watery)
- Stomach pain
- Nausea
- Fever
- Chills

Symptoms often begin 12-24 hours after a person becomes infected and usually last from 2-10 days. In immune suppressed persons, mainly those with chronic liver disease, certain kinds of *Vibrio* bacteria can be very serious.

How is vibriosis spread?

Most people become infected with vibriosis by eating raw or undercooked shellfish (e.g. oysters) during the summer months. People with open wounds can be infected with through direct contact with saltwater. Vibriosis is not spread from person to person.

Who is at risk for getting vibriosis?

Anyone can become ill, but young children, senior adults, pregnant women, and immune suppressed individuals (such as patients on cancer drugs and with organ transplants) are at high risk for illness.

How do I know if I have vibriosis?

A person having diarrhea lasting ≥ 24 hours should consult a doctor for testing.

How is vibriosis treated?

Most people recover without treatment, but diarrhea can cause dehydration so an ill person should drink plenty of fluids. Some infections require medicine. Talk to your doctor to decide what's right for you.

How is vibriosis prevented?

- Use treated water for washing, cooking, and drinking.
- Do not eat uncooked or undercooked shellfish or fish, including ceviche.
- Avoid swallowing untreated water.
- Do not go swimming or use hot tubs if you have diarrhea for at least 2 weeks after diarrhea stops.
- Treat wounds by washing with soap and water as soon as possible and applying a waterproof bandage.
